Abstract

Cortes, Felipe; Ierusalimschy, Roberto (Advisor). **Extrator de Tipos para Lua**. Rio de Janeiro, 2023. 14p. Dissertação de Mestrado – Departamento de Informática, Pontifícia Universidade Católica do Rio de Janeiro.

Inspecting dynamically typed code is hard due to the lack of type information provided. Inspired by this challenge, we built a tool capable of inspecting Lua programs and extracting types from the functions in it. Sustained by the reflection capabilities of the language, it's possible to extract parameter and return values from each function execution and generate a useful report for code documentation and inspection. This document presents the software design and implementation, as well as results obtained by some Lua benchmark programs.

Keywords

Lua; Language; Type; Inspection.

Resumo

Cortes, Felipe; Ierusalimschy, Roberto. **Extrator de Tipos para Lua**. Rio de Janeiro, 2023. 14p. Dissertação de Mestrado – Departamento de Informática, Pontifícia Universidade Católica do Rio de Janeiro.

Inspecionar código dinamicamente tipado é uma tarefa difícil devido a falta de informação sobre tipos. Inspirado por esse desafio, construímos uma ferramenta capaz de inspecionar programas feitos em Lua, extraindo os tipos das funções nele presentes. Sustentado pelas funções introspectivas da linguagem, é possível extrair os valores dos parâmetros e retornos de cada execução de função, gerando um relatório útil para documentação e inspeção. Esse documento apresenta a especificação e implementação do software, assim como os resultados obtidos em alguns programas Lua de referência.

Palavras-chave

Lua; Language; Type; Inspection.

Introduction

There are several reasons that motivate the adoption of statically typed languages. Maintaining large systems built with dynamic types can become a nightmare due to the lack of type information (TAKIKAWA et al.,). Typed languages has also generally better performance because compile-time type information helps generating optimized machine code. However, programmers are frequently left empty-handed when inspecting dynamically typed code while having to re-write systems to a statically typed language if gradually typed languages are not an option.

Inspired by the challenge of inspecting dynamically typed code, we built a type extractor for the Lua programming language. By inspecting a program's execution during runtime, it can generate a detailed report with the types being transfered between functions. We believe that the type extractor can help programmers understand the types in a program's execution, contributing for code documentation, debugging and optimization.

The document is structured as follows. In Chapter 2 we present previous work related to type systems in Lua. In Chapter 3 we describe the software goal. Chapter 4 explain the software modules and how they interact. In Chapter 5 it's shown the software key functions, the modules relationship and basic utilization. In Chapter 6 we present and discuss some results obtained by the type extractor with some Lua benchmarks. Finally on Chapter 7 we present our conclusion and future work.

2

Previous Work

There has been some notable works about Lua type system that we must cite. Typed Lua (MAIDL; MASCARENHAS; IERUSALIMSKY, 2014) has already defined an optional type system for the language. More than enriching documentation, this extension ensures static type safety while preserving Lua idioms. Typed Lua encodes the main data structure mechanism from Lua into arrays, records, tuples and maps. It uses a bracket syntax to denote table types:

Code 1: Insert Typed Lua

```
1 local interface Element
2     info:number
3     next:Element?
4 end
5
6 local function insert (e:Element?,v:number):Element
7     return { info = v, next = e }
8 end
```

The type system is designed to be lightweight and type-safe and extends for typing object, classes and modules by adding type annotations. In Code 1 example, a simple algorithm for inserting numbers in a list is shown using type annotations. The Element interface is defined recursively and referenced twice on the function's header, indicating it's return type. The ? symbol means that *e* is optional and can assume empty values. Although Typed Lua's type system share some parts with other optional type systems for dynamically typed languages, it's design demanded uncommon features due to Lua's characteristics.

Lua Type System has also been explored for scripting optimization with Pallene (GUALANDI; IERUSALIMSKY,). The language design is inspired by optional type systems and it's semantical and syntactical similarity with Lua enables integrating seamlessly with Lua's dynamic code.

Code 2: Pallene Array Sum

```
1 function sum ( xs : { float } ): float
2     local s : float = 0 .0
3     for i = 1 , # xs do
4         s = s + xs [ i ]
5     end
6     return s
7 end
```

As opposed to Typed Lua, Pallene is designed for efficiency. It performs runtime checks to ensure type safety with a particular flexibility. Similarly, Pallene uses type annotations. As shown in Code 2, the function *sum* receives an array of float and returns a single float. Pallene has a built-in interoperability with Lua by sharing its runtime and data-structures. These features allow converting Lua code to Pallene code more easily.

3

Project Scope

Type extraction for dynamic code is a challenging task. This project explores the reflective abilities of Lua to achieve the goal of building a complementary tool to collect type information from a user's program and report this data for documentation, inspection and code migration. The introspective functions of the Lua debug library allow us to inspect names and values of a running program. It also provides a hook mechanism for registering functions to trace the program's execution. As an output the program generates a list describing the function types for parameter and return values.

Lua values can assume several types, specially tables, which is the main data-structure mechanism of the language, and functions, considered as first class values. This type dynamism makes type inspection a challenging task, so in order to reduce this complexity, we chose to follow a merge strategy for types following the Pallene Language type specification. Pallene conventional type system brings simplicity for table types, restricting them as array types and record types and shows a straightforward function type definition.

(ADAPT)Serving as an analysis tool, the type extractor won't make any type validation or restrain the program's execution. The types which could not be inferred will be shown as a dynamic type.

It offers two ways to inspect functions inside a program. A full program inspection is available by passing a lua program as input to the extractor. In this approach, each Lua function will be analysed. An alternative way is to import the extractor as an auxiliary library. By importing the inspection library, the programmer can register specific functions for inspection and select what part of the program they want to analyse. Giving tools for understanding the types relations inside a program helps programmers to debug and optimize dynamically typed code.

4

Project Specification

The objective of the type extractor is to generate a readable report for the user containing the types of parameter and return values of each function in a program's execution. With this objective in mind, we explored the reflection abilities of Lua through four main modules.

A type function to categorize Lua values into specific types. An inspection function to access local variable values, specially parameter and return values and pass them to our type function. A hook module to register our inspection function to be executed in each function call and return event. Finally, a report module to print all type information gathered through the inspection.

First, we want to be able to categorize Lua values into specific types. The Type module is responsible for creating a type specification depending on the value passed. Second, an inspection module is responsible for accessing local variables, specially parameter and return values. Third, a hook module, responsible for registering

Modules

- Type: Element that represents a type
- Inspect - Inspection of local upvalues
- Hook - Manages function hooks
- Report - Generates a friendly report

Development

The type extractor depends heavily on Lua debug library. Our tool make use of the hook mechanism and introspective functions to inspect names and values inside a program execution. The project development is inspired by a rudimentary profiler, specified in Chapter 25 of the Programming in Lua book (IERUSALIMSKY,).

Type Categorize values into conventional types, boolean, integer, string, float, number, array, record, function An array type is defined by the union of the types of each element in the array. This result can be achieved by a map+reduce strategy, creating a new type for each element in the array and merging them by our union function.

Compatibility Matrix

Relational Metamethods

Inspect

Accessing local variables iterating getlocal for each transfered value

Hook

Basic profiler getinfo at hook events

Report

String formatting

Test

Type comparison by an equality function
